SURAT TUGAS
Nomor : 00735/H.2/ST.LPPM/VII/2020

Kepala Lembaga Penelitian dan Pengabdian Kepada Masyarakat Universitas Katolik Soegijapranata Semarang dengan ini memberi tugas kepada:

Nama : Dr. Florentinus Budi Setiawan, ST.,MT (Ketua)
Ir. Suyanto Edward Antonius, MSc (Anggota)
Dr. Ir. Maria Wahyuni, M.T (Anggota)

Status : Dosen Tetap Universitas Katolik Soegijapranata Semarang

Tugas : Penelitian Ristek Dikti tahun anggaran 2020 Skim Penelitian Terapan Unggulan Perguruan Tinggi dengan judul "Perancangan Alat Deteksi Pergerakan Tanah di Daerah Rawah Longsor"

Waktu : 12 Maret – 22 Desember 2020

Penyelenggara : Ristek-Dikti

Lain-lain : Harap melaksanakan tugas dengan sebaik-baiknya dan penuh tanggung jawab serta memberikan laporan setelah selesai melaksanakan tugas.

Demikian surat tugas ini dibuat untuk dapat dipergunakan sebagaimana mestinya.

Semarang, 3 Juli 2020
Kepala LPPM

Abstract—Landslides have caused many casualties and property. High rainfall is a major cause of soil slip. Landslides will usually be preceded by creeping soil movements. Several types of ground motion detectors including inclinometers have been used to detect this state. Proposed method is using laser beam and camera as detector of landslide. As for the benefits for science is the development of monitoring methods using laser light which is very rare or even done so far. Signals in the form of laser beam projection images captured from the camera are sent using the internet network. The image will be processed so that it can be compared with images taken previously. Changes in laser point indicate ground shift. The accuracy of determining the point of the laser beam that spreads when it is received on the target board is corrected using the cluster center method. In addition, the placement of the control plate will make the direction of the laser beam always towards the target plate. The results of the study have concluded that this system can work well and accurately.

Keywords—laser, cluster, acquisition, plate, detector

I. INTRODUCTION

For developing countries, the problem of disaster is one of the obstacles in improving the quality of human resources, given that growth should not be impeded. several types of disasters have made people move from one place to another. less popular disaster but has quite a lot of events is the movement of land that causes landslides. in the tropics, the landslide disaster is ranked third. the physical magnitude of the cause of the landslide can be scientifically measured and can be well predicted. Land shifting occurs a lot and is a complex event and depends on many factors which are sometimes difficult to predict beforehand. It is necessary to breakthrough technologies so that disaster prevention can be improved. With the use of information and communication technology that is efficient and efficient a reliable and efficient system can be obtained. the limited amount of power can be overcome with a simple but efficient telemetry model. An example is using a power on Ethernet system to power an equipment. We need equipment to read soil conditions to be sent to data centers in different places, so that the analysis can be done without having to monitor every period at the ground movement location. in measuring ground motion, the instrument inclinometer is one of the tools often used to measure ground motion and the results are considered accurate. its small dimensions, high sensitivity and accuracy, low power supply, and low cost are the main reasons for using this equipment [1]. But the actual inclinometer can only detect the slope of the land, but it cannot accurately measure the amount of ground shift, in this case horizontal shift. In areas where the land is moving, what is needed is not only the change in the slope of the land, but the value of the shift to the starting point cannot be detected.

Then it is necessary to measure or relevant equipment to measure the amount of land movement in a certain period of time in the horizontal direction. Data about ground movement conditions that can be sent to the monitoring center are signals from translation positions that can be read from sensors mounted near the target plate. The shift signal captured by the sensor can be stored and sent periodically or continuously, according to the required period, or the speed of the ground crawl. The disaster telemetry system with the proposed model is very necessary which can be made at a low cost. The purpose of this research is to produce a telemetry system to monitor ground shifts at low speeds with high quality, but high quality middle-aged soil. in addition, to obtain sensor design methods and telemetry systems for the purpose of monitoring land shifts that are slow moving. The effect is quite significant for the community is in the form of information about the condition of the land that moves, so they can anticipate in advance. It is expected that the output of this research activity is to obtain a laser-based sensor system to be able to detect ground motion that is quite reliable and accurate. Signals in the form of target plate images that are exposed to laser light can be sent using the internet network, so that they can be monitored continuously or periodically. The importance of this research for science is the development of methods of applying sensors using laser light that have not been done so far. The design of a monitoring network system is more integrated on a broader scale, not only limited to areas that are narrow in scope, but can be integrated on a wider system.

II. THE MATERIAL AND METHOD

A. Laser Beam Characteristics

Gaussian rays are magnetic radiometers and transverse monochromatic radiometers the amplitude profile of the electric field is given by the Gaussian function. It reflects the intensity of the Gaussian profile. This is basic Gaussian transversal mode is the most laser output, because the beam can focus on the most concentrated space. While beams like this have refocused the lens, transverse phase dependency; this results in a different Gaussian beam. Electric and magnetic fields the amplitude profile along the Gaussian sphere beam (for certain waves and polarizations) is determined by single parameter (waist circumference). In certain positions, they are at the waist of the predetermined beam, field amplitude and phase determined.
The arbitrary solution of the paraxial Helmholtz equation can be said to be a combination of the Hermite-Gaussian mode. Amplitude profile can be separated by x and y using Cartesian coordinates. Anytime the point on the z-beam of this mode includes a Gaussian factor that is similar to the basic Gaussian mode. Additional geometric factors for the specified mode. But the different modes are different from Gouy. The phase in which the transversal profile is generated because the mode superposition develops in z, whereas propagation each Hermite-Gaussian mode still has the same shape along the beam. Although there are other possible capital breakdowns, this is the most useful family solution to this problem involves compact rays, that is, optical power close enough along the axis. Even when it's laser does not operate in basic Gaussian mode, power is generally found among the lowest order modes decomposition, because the higher sequence mode will surpass the laser resonator.

The use of a laser beam is needed to obtain measurement accuracy. Therefore it is necessary to place a light transmitter that is strong enough to not change easily by changes in weather and humidity.

Ground motion is the process when the mass of an earth's material moves by Earth's gravity either slowly or rapidly from one place to another. The ground movement occurs as a result of disturbed slope stability, because the driving force of the land which is a landslide exceeds the holding force. This can occur because of an imbalance of forces at ground level and trigger external forces acting on the slope. Strength in soil is influenced by soil type conditions; soil density; the level of shear strength of each soil parameter and underground water flow. Meanwhile the external forces that can influence the movement of the soil are the load acting on the ground, the rainwater entering the ground and the slope angle.

In general, the character of slopes is divided into two types, namely unlimited slopes and limited slopes. Slope stability can be seen from the safety figures from the slope condition analysis. The slope will be considered unstable if it has a safety factor of less than one (FK < 1). Safety figures for slopes are considered stable if the safety factor is more than one (FK > 1).

C. Centre of Gravity

Clustering is a grouping of objects so that objects in the same group are more similar to each other. Laser beam that projected into target plate could be recorded with CCTV camera. Diameter of laser beam projection on target plate was around 3 centimeters. Center of laser beam projection...
have to be calculated as instantaneous center. Picture file that recorded contains many pixel that representation of laser beam projection. There are many pixel with same color (green). Center of pixel group could be calculated using center cluster method. For three pixel denoted by A, B and C could be calculated their center.

![Center cluster of three pixel](image)

Cartesian coordinate of pixel A, B and C shown in table I. Position of pixel A, B, and C distributed around center.

<table>
<thead>
<tr>
<th>Pixel</th>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>B</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td>C</td>
<td>6</td>
<td>2</td>
</tr>
</tbody>
</table>

Position of center could be calculated as following formula:

\[
x_{\text{Center}} = \frac{x_A + x_B + x_C}{3} \\
y_{\text{Center}} = \frac{y_A + y_B + y_C}{3}
\]

Center of this cluster could be easily calculated, then the center coordinate is (3,3). Greater amount of pixel with green color detected could be grouped into a cluster. By using same method, center of cluster could be calculated. Clusters include groups with small distances between cluster members, dense areas of data space, intervals or certain statistical distributions. The centroid of a finite set of \( k \) is

\[
C = \frac{x_1 + x_2 + x_3 + \ldots + x_k}{k}
\]

The k-Means algorithm does clustering by putting data points into clusters whose closest center is located. The quality of the k-Means algorithm is very dependent on the selection of the initial \( k \) center points of the cluster. This method is simple and fast, but can result in loss of correlation between dimensions in the data set. The point of representation in this research algorithm was made with a density-based approach. Initially the algorithm looks for core points in the data set and then groups core points that reach density with each other into a group. Each group is represented by a representation point that is in the middle of the group. Because the representational point represents the core point and is in the middle of the core point, it is most likely that the initial center point of the cluster produced is already in the center of the cluster.

Space distance is used to calculate the distance between data and centroid. Euclidean Distance Space Spelling. Euclidean space distance is often used in distance calculation, this depends on the results obtained is the shortest distance between the two points calculated.

![Center of cluster](image)

![Control plate for adjusting laser beam direction and reduce diffraction](image)

III. RESULTS AND DISCUSSION

At first the laser beam is fired from a relatively stationary place, towards the target plate located in a moving area. To keep the direction of the laser beam from changing, a plate is installed between the laser and the target plate. Laser beam widening can be reduced by reducing the laser beam widening, through a filter in the form of a 5 mm diameter hole in the control plate. This beam projection is too thick for its center to be detected, due to the long distance between the laser source and the monitor metal plate.
Diameter of laser beam projection on target plate for distance between laser source to target plate of 8.8 meter is 7.8 cm. This beam projection is too thick for its center to be detected, due to the long distance between the laser source and the monitor metal plate.

Thickness of laser beam projection is reduced by using control plate between laser source and target plate. Control plate is installed at distance of 52 meter from laser source. Control plate is installed in a stable position, on south side wall of the sport hall.

Laser beam projection on the monitor metal board is too big to decide size of landslide per certain period. In order to obtain more precision measurement, central cluster method is applied. Based on imaging signal processing system, by using inverted signal and center cluster method, the center of beam is calculated. Center of laser beam will be change when there are any landslides on pole A. If projection of laser beam is reduced, there is need adjustment on laser source direction. It will be happen when the laser beam changes its direction because of climate or other condition.

By using signal processing calculations, the image will be reversed to get a lot of contrast from the image. But the transition between white and black areas still appears in this picture. A high pass filter is applied to get a lot of contrast. The center of the beam is calculated using the centroid method. The movement of the point obtained represents the movement of the ground.

ACKNOWLEDGMENT

This work was supported in part by the Higher Education, Ministry of Research and Higher Education, Indonesia 2019-2020 fiscal year and is part of the research landscape detection using laser beam. A thank you also addressed to the Institute of Research and Community Services at the Soegijapranata Catholic University for providing facilities so that the research process can run smoothly.
