TOWARD WATER FRIENDLINESS IN BATIK PRODUCTION: Addressing the key factors on water use for batik production in Jarum village, Klaten Regency, Indonesia
Environmental Science and Pollution Research

Dear Ms Handayani,

I am pleased to tell you that your work has now been accepted for publication in Environmental Science and Pollution Research. This letter serves as an acceptance certificate. Your article has been sent to the production service and you will receive the proofs soon.

If you have any question, please contact Dennis Villahermosa + dennis.villahermosa@springer.com

Thank you for submitting your work to this journal.

With kind regards,
Dr. Philippe Garrigues
Managing Editor

Abstract:	<p>The Indonesian batik is a cultural product recognized as Intangible World Heritage by UNESCO. However, its production by Small and Medium Enterprises has been raising environmental problems, including water pollution. Since water is vital for humans and batik production, deterioration of its quality affects the people, ecosystem, and batik sustainability. The water scarcity and the emerging concept of circular economy show that a regenerative system that focuses on resource efficiency is essential to replace the current linear production system. A previous study was conducted to examine the role of water in batik production. However, a complete picture on the water use in batik production is required as it will imply to water sustainability, from the experts' perspectives. Therefore, this study identified the factors influencing water use for batik production based on perspective of the experts in combination to craftsmen's experience using a qualitative Delphi method with seven experts on batik and water technology. The result indicates identified challenges that influence the water use for batik production, and four aspects that need to be addressed in order to realize water friendly batik production. Finally, three key factors of actor, system and technology were concluded if the circularity of water use in batik SMEs will be realized.</p>	
Response to Reviewers:	<p>Reviewer comments: You have to rewritten the conclusion. Add the theoretical and empirical implication based on the result of your research. Add the managerial implication. Overall, I still see this paper more like project report than a paper. I suggest you to arrange the data as well as the explanation so we can see the scientific contribution more clearly.</p> <p>Response: Dear respected reviewer, Thank you for your comment and suggestion. Below, we provide our response to your comment which is indicated by blue font color in the manuscript. Thank you very much for your valuable comments to improve our manuscript for publication.</p>	

	<p>The theoretical, empirical, and managerial implications of the study are indicated in the conclusion as provided below:</p> <p>"Four aspects that need to be addressed in order to realize water friendly batik production have been identified, i.e. educating batik craftsmen to increase environmental awareness collectively, ensuring water use monitoring and evaluation, controlling product quality through green batik certification, and introducing appropriate water technologies to the craftsmen. Those four aspects could be summarized into three key factors, i.e. the actor that is represented by batik craftsmen, while the monitoring, evaluation, and product quality control are represented by the system, and the last is the role of water technology. Well educated and skilled craftsmen along with good system and appropriate technology will would be important to the realization of circularity of water for batik production. This study contributes an insight on how water is utilized in the traditional batik-making process in Indonesia which is still understudied so far. Detailed accounts on factors determining the water use in the industry provides a new understanding on the interaction among factors as well as the importance of each factor. On the empirical side, these new understandings can be used as a guideline for the stakeholders to use the water resources in a more sustainable way. Due to the fact that most of traditional batik industries are small scaled and located in a cluster with a limited stock of water, a communal water management model will be a suitable option. The implementation of communal water management model along with monitoring system by the decision makers will support the industry in coping with the increasing water needs due to the ever-increased market demand of the product and realizing a greener batik industry."</p> <p>We also thank you for your suggestion on data arrangement. However, we shall note that qualitative research is usually descriptive, which is rather different from quantitative ones that might include graphics or statistical analysis result. Therefore, in this study we could present tables and pictures.</p>

To.
Editorial Board
Environmental Science and Pollution Research

Dear Editors,

Hereby we submit our manuscript entitled "Toward water friendliness in Batik production: Addressing the key factors on water use for batik production in Jarum village, Klaten Regency, Indonesia" to Environmental Science and Pollution Research's **call for paper: *Circular Economy for Global Water Security***. This manuscript is written by Widhi Handayani, Budi Widianarko, and Alberta Rika Pratiwi from Satya Wacana Christian University and Soegijapranata Catholic University, Indonesia.

We have been conducting researches on batik, a cultural product of Indonesia, which has been produced by Small and Medium Enterprises (SMEs). While in the positive side, its production could support the economics of the country, on the other side, it creates water pollution. Our previous researches indicated the higher portion of Grey Water Footprint in comparison to Blue Water Footprint which means the production consumes a huge of water to dilute the wastewater. This study focuses on identifying the factors which influence water use for batik production, explaining the problems related to SMEs' water use, and proposing a qualitative model to address the issues to implement the circular economy concept for water use in batik production SMEs.

We hope this manuscript could be reviewed for publication in this journal. Thank you for your attention.

Sincerely,
Widhi Handayani

Abstract

The Indonesian batik is a cultural product recognized as Intangible World Heritage by UNESCO. However, its production by Small and Medium Enterprises has been raising environmental problems, including water pollution. Since water is vital for humans and batik production, deterioration of its quality affects the people, ecosystem, and batik sustainability. The water scarcity and the emerging concept of circular economy show that a regenerative system that focuses on resource efficiency is essential to replace the current linear production system. A previous study was conducted to examine the role of water in batik production. However, a complete picture on the water use in batik production is required as it will imply to water sustainability, from the experts' perspectives. Therefore, this study identified the factors influencing water use for batik production based on perspective of the experts in combination to craftsmen's experience using a qualitative Delphi method with seven experts on batik and water technology. The result indicates identified challenges that influence the water use for batik production, and four aspects that need to be addressed in order to realize water friendly batik production. Finally, three key factors of actor, system and technology were concluded if the circularity of water use in batik SMEs will be realized.

Keywords: Batik production, Small and Medium Enterprises, circular economy; water-friendly, water use

Introduction

The Indonesian batik is one of the ethnic products recognized as the Intangible World Heritage by UNESCO. Batik is a cultural product created by Indonesians for a long time. For instance, the term *Tulis* (handwriting) was first mentioned in 1518 (Elliott, 2004). Although it was previously worn mainly by the royal family, it became a common product from 1850, with best works produced between 1850 and 1939 (Elliott, 2004). With its massive production, batik has contributed to the economics of the Indonesians, particularly in the Small and Medium Enterprises (SMEs).

According to Weerasiri & Zhengang (2012), SMEs are a leading group in global economic activities. Specifically, they play an essential role in supporting the economy in Asia Pacific countries. Apart from supporting economic growth, SMEs can absorb labor that cannot be accommodated by the formal sector (Tambunan, 2019). According to Capri (2019), 99.9% of businesses in Indonesia comprises micro and small-medium enterprises. In 2017, there were about 57 million micro and SMEs operating in Indonesia. Statistics show that about 60% of Indonesia's GDP is contributed by micro and small-medium enterprises (Capri, 2019; Tambunan, 2019). Despite their contribution to economic growth, SMEs have a significant negative impact on the environment (del Brio & Junquera, 2003; Hillary, 2004; Vasilenko & Arbačiauskas, 2012).

It is generally understood that natural resources are important for economics as production and consumption processes depend on natural resources in addition to energy, and the use of the materials in general usually ends up in generating waste. The use of natural resources will bring economical, environmental, and social consequences, and the intensity will depend on some factors, such as the amount of the natural resources used, the natural resources management, and the location from which the natural resources originate. Therefore, efforts are required to improve the efficiency and productivity of natural resources along their life cycle (OECD, 2020). Recently, in order to address the problem caused by the linear model of production, i.e. take-make-dispose which usually ends up in generating waste and resource inefficiency, a restorative or regenerative industrial system called

49 circular economy has been proposed. The circular economy seeks to increase efficient use of resource by utilizing
50 it in a circular cycle in order to avoid or minimizing waste generation, including the use of renewable energy,
51 promotes materials reuse, less use of toxic chemicals, and less waste generation (Ellen Mac Arthur Foundation,
52 2013). In addition, it seeks to maximize the value of materials use in the process of economics, and reducing
53 material consumption (OECD, 2020). A review conducted by Lieder et al (2016) highlight three major aspects of
54 circular economy, i.e. waste and environmental which focuses on minimizing the environmental impact, resource
55 scarcity that motivates the regenerative use of resources, and economic benefits to maintain
56 companies' sustainability and increasing profit. Korhonen et al (2018) writes two contributions of circular
57 economy, i.e. high value and quality of material cycles in a new design and provide a possibilities in sharing
58 economy along the sustainable production, while identifying six main challenges of circular economy
59 implementation. In spite of its limitations and challenges, the previous studies indicated the potential of circular
60 economy in order to conserve natural resources and hence, maintain its sustainability.

61 In recent years, water resource has been a big challenge in the world's economics (Hoekstra, 2014). In 2007, the
62 UN highlighted the need to address water scarcity urgently. It is predicted that in 2025, about two-thirds of the
63 world population will be living under water stress. Statistics also show that around 1.8 billion of the world's
64 population will live in regions with absolute water scarcity (UN Water, 2007). In terms of economics, water
65 scarcity hurts a broad spectrum, including bilateral international trade, businesses, food production, and the
66 tourism industry (Guarino, 2017). Therefore, there is a need for an urgent move to sustainable water use (Hoekstra,
67 2014). According to UN Water (2007), the amount of water used for industries, agriculture, and domestic activities
68 will increase by 60-90% in 2050, unless water productivity increases.

69 Challenge on water resources are also reported in batik SMEs across Indonesian regions, including Klaten
70 (Kristijanto et al., 2011; Mukimin et al., 2018; Handayani et al., 2018). These challenges include water
71 inefficiency, the absence of 3 Rs (reduce, reuse and recycle) implementation, and lack of waste water treatment.
72 Since batik industry is heavily dependent on water resource, inefficient use of water and water quality deterioration
73 could affect its sustainability. Recent batik studies related to water resource are focused on creating a technical
74 model for green batik industry (Yaacob & Zain, 2016), improving and optimizing the batik wastewater treatment
75 process (Sutisna et al., 2017; Mukimin et al., 2018), calculating batik water footprint (Handayani et al., 2019) and
76 proposing strategies to manage batik wastewater based on environmental, economics, and social aspects
77 (Sulthonuddin & Herdiansyah, 2021). It is clear that studies on batik are still focused on the end of pipe approach,
78 especially in order to solve the problem of wastewater. In the context of circular economy, in order to put in the
79 circular cycle the water should be processed to be reusable, instead of being processed to meet certain quality
80 criteria followed by its disposal to environment. The circular economy indicates that in order to achieve efficiency,
81 it is also important to focus on how the water should be managed since the beginning of the process or since the
82 opening of pipe. This understanding highlights the importance of identifying the factors that influence water use
83 for batik production.

84 Previously, a Focus Group Discussion (FGD) involving batik craftsmen identified four factors that influence the
85 use of water, including the production scale or ratio of water use and the quantity of batik produced, the type of
86 materials used, the habit of batik workers, and the availability of water technology (Handayani et al., 2021).
87 However, in order to get the complete picture of the water use in batik production and its implication on water
88 resource sustainability, a complementary survey involving the experts of batik production needs to be conducted.
89 Therefore, this study explored water use by batik SMEs based on experienced experts and discussed their
90 experience to gain more comprehensive information. The objective of the paper is identifying the factors that
91 influence water use for batik production based on expert's perspective, and combining the craftsmen's daily
92 experience to experts' technical judgement in order to formulate a recommendation to realize circularity of water
93 use in batik production.

94 **Method**

95 This study was conducted using qualitative Delphi method. According to Linstone & Turoff (2002), the Delphi
96 method is characterized by a structured group communication process which effectively allowing group of
97 individuals to deal with a complex problem. It is indicated by Skumolski et al (2007) that Delphi method was
98 conducted by distributing questionnaires to experts by email, followed by collecting the experts' responses,
99 repeating this process to some rounds. The data collection could be finished when answer for research question is
100 found or reaching a specific consensus or achieving certain stability on panellists' responses (Rowe & Wright,

101 1999; Skulmoski et al., 2007), and finally followed by data analysis, including quantitative analysis (Skumolski et
102 al., 2007).

103 Since statistical aggregation and quantitative analysis are considered to be necessary for a Delphi procedure (Rowe
104 & Wright, 1999; Skulmoski et al., 2007), it seems that Delphi tends to be quantitatively performed. In fact, although
105 quantitative Delphi method has been conducted, such as in the studies on meat consumption (Chamorro et al.,
106 2012) and food safety management (Ilic et al., 2017), the Delphi has also been performed along with qualitative
107 method for community-engaged research (Brady, 2015), Participatory Action Research in health leadership
108 (Fletcher & Marchildon, 2014), and batik study (Pujotomo et al., 2018). However, both methods show similarity
109 in using experts as panellist for collecting information (Skulmoski et al., 2007; Fletcher & Marchildon, 2014;
110 Brady, 2015; Ilic et al., 2017; Conchin & Carey, 2018).

111 In addition to Delphi, qualitative method was used for this study. The qualitative method is selected because its
112 characteristics which could find deeper understanding on human behavior, perspectives, and experiences of
113 people. According to Mohajan (2018), it is the qualitative method that could systematically describe and interpret
114 an issue or phenomenon based on the perspective of the individual or population, which finally, by its inductive
115 inquiry, could generate new concepts and theories. Since water use for batik is related to human activities, and
116 “*how the batik craftsmen use water?*”, as well as “*why do they use the water that way?*”, might be influenced by
117 their perspectives and experiences with water, the qualitative method becomes relevant to be used for this study.
118 Furthermore, as in this study Delphi method which involves the participation of expert is used, it is an advantage
119 to grasp deeper information on water use for batik production based on the knowledge and experience of experts,
120 as they could provide deeper understanding on the phenomenon, as indicated by Brady (2015).

121 The first step involved developing a research question similar to the one in the previous study (Handayani et al.,
122 2021). Specifically, the question was on *the key factors that influence water use by batik SMEs*. However, it was
123 broken into eleven questions to examine five topics, i.e. (1) the importance of water for batik production, (2) the
124 required water quality, (3) the required water quantity of water and whether the production use water excessively,
125 (4) the key factors which influence the water use by batik SMEs, and (5) possible efforts to raising awareness of
126 batik craftsmen on using the water with special concern.

127 The second step involved looking for experts in batik. The criteria for the experts were explained by Skumolski
128 et al. (2007). Specifically, (1) the panelists should have knowledge and experience on batik, (2) be available and
129 willing to participate in the research, (3) sufficient timeframe, and (4) effective communication. Considering that
130 Delphi method involves the expert, the sample for the study are usually determined purposively, which is very
131 similar to the qualitative methods. As indicated by Brady (2015) instead of having a number of samples for
132 generalization purpose, purposive sample of individuals on specific expertise is preferred in Delphi method.

133 In regard to recruitment, we make a list consists of the name of researchers on batik based on their published
134 researches in journals. In term of expertise, we prefer to list researchers who have published two or more articles
135 on batik and environmental context or have been conducting research on batik for years, which indicates the long
136 experience they have on batik and environmental issue. Based on the selection, we decided six candidates to
137 contact, which consists of two researchers from Balai Batik Yogyakarta, and the rest were academicians from
138 universities in Indonesia. Among those six candidates, three candidates agreed to participate in the research, two
139 other researchers could not be contacted using their email indicated in their articles, while the rest confirmed that
140 she could not participate the research. Using the snowball technique, we get five more candidates to follow up.
141 One of them did not response to our invitation, and four of the candidates agreed to participate. Therefore, in this
142 research, seven batik experts were involved. They were (1) two senior female university researchers of doctoral
143 degree and a female university researcher of master degree who have been conducting researches on batik and
144 mentoring their students on batik research; (2) a female university researcher of master degree who is also an
145 expert on batik art and activist for women batik artisan’s empowerment; (3) a male practitioner on water and
146 wastewater treatment for textile industries by more than five years experience; (4) and two male and female senior
147 researchers from Balai Batik Yogyakarta. Essentially, the Balai Batik Yogyakarta is the Government’s Agency
148 for Batik Research and Development, and therefore, their involvement is relevant. In order to keep anonymity of
149 experts, the identity of participants was not shared among them.

150 The third step is collecting the data. As this research was conducted using a qualitative approach, instead of
151 distributing the questionnaires as suggested by Skumolski et al. (2007), a modified Delphi technique was
152 conducted in the format of Focus Group Discussion (FGD), without sacrificing the structured communication

153 principles of Delphi method, i.e. feedbacks of individual contributions of information and knowledge; assessment
 154 of the group judgment or view; and opportunity for individuals to revise their views. By seven participants, the
 155 FGD is suitable to conduct. It is indicated by Nyumba et al (2018), the participants for FGD could be in the range
 156 from six participants to fifteen participants, although more than twelve participants will consequently lead to
 157 difficulties in managing the group. Therefore, seven participants is appropriate for this study, particularly because
 158 the limited number of experts on batik and environmental context as well as their willingness to participate in the
 159 study. Furthermore, the FGD format enables an open and comfortable discussion among the participants with the
 160 role of researcher as moderator for the discussion (Nyumba et al., 2018). Therefore through an FGD, the structured
 161 communication principles required for Delphi can be met. The FGD was conducted online by the Google Meet
 162 platform for about 150 minutes to obtain panelist's input and opinions using prepared questions. Afterward, they
 163 examined the previous result based on the opinion of batik craftsmen presented by the moderator of the group.
 164 This step was conducted to reconcile the understanding of experts and the experience of batik craftsmen and
 165 workers. This FGD was run until no new information produced from the discussion (Nyumba et al., 2018), which
 166 is in line to the Delphi, i.e. when research question is answered, specific consensus or panellists responses'
 167 stability is achieved (Rowe & Wright, 1999; Skulmoski et al., 2007). As no information was exchanged after the
 168 150 minutes FGD, therefore it could be expected that data collection using this one round FGD is sufficient.
 169 During FGD, the meeting is recorded. The data collected was transcribed and analyzed descriptively by qualitative
 170 data analysis technique, and the results are narratively presented.

171 **Results and Discussion**

172 This section describes the results obtained from FGD with the experts, which reflects the experts' experience with
 173 batik craftsmen. The comparison on the experts' perspectives on the key factors of water use for batik production
 174 to the batik craftsmen perspectives which has been previously published will also be conducted in this section. In
 175 addition, the results obtained from this study will also be compared to other relevant studies on batik. Finally, the
 176 results found from this study will be discussed with results from other studies in textile, because batik is quite
 177 specific, and in the context of circular economy.

178 **Results**

179 *The importance of water for batik production*

180 The experts highlighted the importance of water for batik production. Water is considered to be the main resource
 181 for batik making process. This means production might be disturbed in case water is unavailable. Table 1 shows
 182 the opinions of experts reflected from their own experience with batik craftsmen and workers.

183 Table 1. The importance of water for batik production

No.	Facts about the importance of water based on the opinion of experts
1a	Water is the main resource for batik production.
1b	Water is used throughout the process, from cloth mordanting until final washing.
1c	The unavailability of water could affect batik production continuity.
1d	The batik craftsmen are interested in using water for free or at no cost.
1e	If water available at no cost, the batik craftsmen and batik workers tend to use it abundantly.
1f	The batik craftsmen are interested in free cost regarding (waste)water disposal.
1g	The batik craftsmen and batik workers tend to use water immeasurably.

184

185 According to Table 1, the batik craftsmen prefer to use water obtained abundantly and immeasurably. It is
 186 indicated by Susanty et al. (2015) that water use for batik production is diverse as there was batik SME who uses
 187 350,000 L of water per month while another SME uses 3,000 L per month, by a different production scale.
 188 Nevertheless, they showed difference in term of water use efficiency, as there was a SME in Pekalongan who uses
 189 10,000 L/month of water to produce 200 pcs/month batik which equal to 50 L/pc, while another SME in Solo uses
 190 4,000 L/month of water to produce 600 pcs/month of batik or equal to 6.67 L/pc (Susanty et al., 2015). Harren
 191 (2019) also found this phenomenon in Ciwaringin batik, West Java and indicates that there are outside and
 192 unknown qualitative variables which might influence the water use by batik craftsmen. It is the phenomenon
 193 highlighted by the experts in how the batik craftsmen are usually using water abundantly or immeasurably, not
 194 only in Central Java, but also in West Java. However, the experts also indicated this pattern of behavior relates to
 195 their access to water and their need to pay for the water. When water is available for free or at no cost, they will

196 use it abundantly. It is common to find in SMEs that they do not incorporate the cost for water in the product's
 197 price, or even they do not calculate the cost for water which in reality they pay in the form of electricity to pump
 198 the water from their boreholes. This situation might influence the batik craftsmen's behavior on using water. In
 199 addition, they are always reluctant to pay for wastewater treatment. This case might be related to their
 200 understanding that wastewater treatment needs a specified technology, while the craftsmen are usually limited in
 201 term of educational level. Based on our observation and experience, most of the craftsmen in Klaten graduated
 202 from primary or secondary school, and only a few who graduated from higher education level. Furthermore, their
 203 understanding on wastewater technology is usually relates to its high cost, which could be another barrier for them
 204 to invest for wastewater treatment technologies.

205 Table 2. The water source for batik production

No.	Facts about the water source and water quality for batik production
2a	Freshwater from the well is of the best quality for batik production.
2b	Rainwater is not very good for batik.
2c	If freshwater from the well is unavailable, the batik craftsmen can use water from the Perusahaan Daerah Air Minum (The government's agency for drinking water provision).
2d	Although it is quite rare, there are craftsmen from some batik centers who use surface water from the river to wash the batik cloth.
2e	The used water from certain process might be reused for other processes that do not require clean water.
2f	Despite the quality, batik craftsmen will consider the cost of getting water to consider the water they will use.

206

207 Based on experts' experience, the best water source often used by the batik craftsmen was from the well, dug and
 208 deep. In case the well is not available, they use water from Perusahaan Daerah Air Minum (The government's
 209 agency for drinking water provision). In Jarum village, the batik craftsmen usually use water from wells and not
 210 from PDAM. This is because PDAM was not operating in the village. According to the experts, the well's water
 211 is the best choice mainly because its hardness is usually low, affecting quality, particularly for the natural batik
 212 dyeing process. In natural dyeing, mordants are required to fix the color onto the cloth due to the instability of
 213 natural dyes to light exposure and washing (Christie, 2015). Some mordants frequently used for natural batik
 214 dyeing include alum, lime, and copperas (Handayani et al., 2020). Since hard water often contains calcium or
 215 magnesium ions, water quality may negatively affect the batik's color quality. However, the well of Jarum people
 216 often contains calcium, which may negatively affect the quality of the product. According to Patil et al. (2019),
 217 hard water showed a detrimental effect on textile dyeing when the coloration involves reactive dyes. This is
 218 because the depth of shade decreases with the increase in hardness, indicating the need for a water softener or
 219 sequestering agent. Since hardness is strongly related to water quality, one cannot expect a "standard" quality of
 220 batik. This is because the quality might vary over time, and using a water softener or sequestering agent means
 221 spending more money.

222 According to the experts, neutral pH and low metal levels affect color quality during the dyeing process. A low
 223 level of pH or acidic water tends to form a yellowish color. In comparison, alkaline water often produces a red
 224 color. Furthermore, a higher level of iron in the water produces darker colors, which is in line to the report of Ali
 225 et al (2010) that the use of ferrous sulphate or copperas as mordant for natural dyeing resulting dark color of the
 226 fabric.

227 Although the expert confirms that rainwater is not appropriate for batik production, the craftsmen from Jarum
 228 have been harvesting it, both for daily needs and production (Handayani et al., 2021). This habit is attributed to
 229 the fact that they suffered from water scarcity before 2006. They tried to obtain water from whatever source,
 230 including their wells, neighborhoods, and rainwater (Handayani et al., 2021).

231 *How do the batik craftsmen use water for production?*

232 All experts agreed that most batik craftsmen often used water excessively or immeasurably. This is particularly
 233 the case with craftsmen who have not yet practiced cleaner or green batik production. Table 3 shows the opinion
 234 of experts regarding the water use behavior of batik craftsmen.

235 Table 3. The water use behavior of batik craftsmen

No.	Water use behavior of batik craftsmen
3a	The batik craftsmen often use water resources excessively or immeasurably, mainly if they have not practiced yet cleaner production or green production of batik.
3b	There is no standard in using water for production among batik craftsmen.
3c	Lack of technical knowledge contributes to the excessive use of water.
3d	The craftsmen prefer to fill the water tank in full, particularly for washing.
3e	The craftsmen prefer to collect the batik clothes in a certain quantity before wax removal.
3f	The behavior seems to be related to satisfaction, i. e., the craftsmen are satisfied if they could use water in huge quantities.
3g	The behavior of batik craftsmen in using water also relates to the free cost of getting water.

236

237 According to the experts, the behavior of the craftsmen in using water is influenced by several factors. For
 238 instance, free water leads facilitate excessive use because of thinking it is found easily. For this reason, they fill
 239 the water tank, particularly for washing. Furthermore, the lack of technical knowledge, such as removing
 240 hydrochloric acid as a fixing-agent with much water instead of an alkaline solution, affects them. The craftsmen
 241 also prefer collecting the clothes for certain amounts before wax removal. This is in line with Handayani et al.
 242 (2020), which established that the owner often collects up to 70 or 80 sheets to be processed for wax removal
 243 once. The water used for wax removal, followed by the washing process to produce 50 sheets of batik per day by
 244 a large-scaled batik SME, was 575 L/day (Handayani et al., 2018). However, there was also a different pattern
 245 indicated by batik SMEs that focus on wax removal anytime regardless of the quantity produced. These habits
 246 indicate a different use of water. It can be more efficient suppose the batik clothes are collected and finished once,
 247 instead of conducting wax removal every day.

248 According to an expert, the huge water consumption is attributed to a lack of set standards. However, another
 249 expert stated that the government represented by the Ministry of Industry and Trade of Indonesia (2019) has been
 250 publishing a regulation on a standard for green batik production, specifically 50 L/m²/color and 10 L/m² for
 251 synthetic and natural dyeing, respectively. The water needed for batik produced by synthetic dyeing was 10
 252 L/sheet calculated from dyeing to the wax removal process. This might be suitable suppose the calculation was
 253 conducted with a direct water use approach. From the 16 SMEs spread in Yogyakarta, Solo, and Pekalongan, one
 254 of them consumes 350,000 L/month of water to produce 2,624 pieces of batik per month, while another one used
 255 3,000 L/month of water to produce 90 pcs per month (Susanty et al., 2015). This means water consumption by the
 256 first SME was 133.38 L/pc, while the second SME was 33.33 L/pc. The information provided by the expert
 257 contravened Susanty et al. (2015). However, 10 L/sheet was only from dyeing to wax removal processes, while
 258 Susanty et al. (2015) indicate the water consumed in the entire batik making process. This comparison implies
 259 variations in water consumption for batik production among SMEs, often calculated based on the direct water use
 260 approach. Nevertheless, in relation to the former debate on batik production standard, it is possible the batik
 261 craftsmen in Jarum have not been get informed by the regulation of Ministry of Industry and Trade of Indonesia
 262 (2019). If this situation occurs, a meeting to provide information to the craftsmen regarding the implementation
 263 of Green Batik Industry indicated by the government would be necessary.

264

Table 4. Key factors on water consumption for batik production

No.	Key factors that influence water consumption for batik production
4a	Batik design
4b	The number of dyes used for the batik-making process
4c	Dyeing frequency
4d	The habit of batik craftsmen in using water
4e	Type of dyes used, i. e., natural dyes or synthetic dyes

265

266 Table 4 shows the key factors that influence water consumption for batik production. According to the experts,
 267 one of the key factors is the batik design, which relates to the complexity of the batik, for example, where the
 268 batik is of the full motif (Fig 1a) or not-so-full motif (Fig 1b). The design also relates to the number of colors
 269 applied to the cloth. The more the colors applied, the more water required to prepare the dyes, both natural and
 270 synthetic. This also depends on the dyeing frequency, which can be more frequent in line with dye application.

271 Fig 1. Samples of batik design of full motif (1a) and not-so-full motif (1b)
 272 (Source: personal documentation)

273 Compared to the arguments of batik craftsmen, the key factors that determine water use was different from the
 274 experts. The previous FGD with the craftsmen identified four key factors that affect the water uses for batik
 275 production, i.e. (1) the ratio of water use to the number of batiks produced, (2) the materials used, (3) the water
 276 uses habit of the craftsmen, and (4) water technology (Handayani et al., 2021). The materials used in batik
 277 production, such as the type of dyes and water use habit, are similar factors identified by craftsmen and experts.
 278 However, the batik design that includes dyeing frequency and the number of dyes for the batik-making process
 279 was not identified by the craftsmen. Similarly, the water consumed per sheet of batik produced and technology
 280 was not identified by the experts.

281 **Table 5. Possible efforts to reduce water use in batik production**

No.	Possible efforts to save water for batik production
5a	Increasing awareness of the craftsmen that water is vital for batik, hence its sustainability is essential to support batik sustainability.
5b	Increasing awareness of batik craftsmen that batik as cultural heritage should be directed to eco-friendly production.
5c	Promoting green product certification and the advantages or incentives the craftsmen will receive suppose their products are certified.
5d	Promoting water measurement as a different activity from batik production.
5e	Calculating the water use cost, incorporating the cost for product pricing, and explaining the economic benefit obtained if the batik craftsmen could save water or use less water.
5f	Creating a Standardized Operating Procedure for batik production
5g	Avoiding the disposal of "unused" dye solution
5h	Using the alkaline solution to neutralize acidic fixing-agents instead of using a large amount of water.
5i	Improving water quality, particularly reducing the hardness or minerals contained in the water.
5j	Improving dyeing technology.

282 Table 5 shows some of the efforts to reduce water use in batik production. The first effort is raising the awareness
 283 of the craftsmen regarding the vitality of water for batik. This may lead to the conservation of water resources to
 284 maintain their sustainability. Furthermore, it is important to ensure cleaner production to improve batik quality
 285 and preserve it as Indonesia's cultural heritage. The government has been promoting green product certification
 286 to draw the craftsmen's attention to adopt cleaner batik production. In this regard, water should always be
 287 measured to monitor its use during production. This can help the craftsmen calculate their monthly expenditure
 288 for water resources and how much money they could save, suppose they use it more efficiently. Educating the
 289 craftsmen to incorporate water resource cost in product pricing is vital because they often ignore the cost for water
 290 in product pricing due to the "water is free" mindset.

291 The experts also highlight the importance of creating a Standardized Operating Procedure (SOP) for batik
 292 production. This SOP is required to guide the batik craftsmen to use resources efficiently during production. To
 293 increase efficiency, the disposal of dye solutions and neutralizing the fixing-agent by water are not suggested.
 294 Instead, the dye solutions should be used completely, and the acidic fixing-agent neutralized using an alkaline

295 solution instead of water. Finally, technology is important to improve water quality in the demineralization and
 296 dyeing process improvement.

297 *Reconciling the expert and batik craftsmen in water use for batik production*

298 This study shows that water consumption for batik production is influenced by factors related to the batik itself
 299 and the craftsmen. For instance, design (Table 4) affects the number of colors used and dyeing frequency. The
 300 second factor may relate to the habit of batik workers in using water (Table 4). According to Table 5, there are
 301 other factors apart from those mentioned in Table 4. The four key factors highlighted in the previous study include
 302 water use habits, the materials used, which may consume less water, production scale, and water technology
 303 (Handayani et al., 2021). Table 6 shows the combination of factors reflected by both the experts based on this
 304 study and the craftsmen based on the previous study (Handayani et al., 2021).

305 **Table 6. The key factors that influence water use for batik production**
 306 **(based on expert and batik craftsmen)**

No	Key factors	Interpretation
1.	<ul style="list-style-type: none"> • Lack of understanding of water conservation to sustain batik (experts) • Lack of understanding that cleaner production is required to realize eco-friendly batik (experts) • Lack of understanding that water resources should be considered to incorporate into product pricing, instead of free public goods. (experts) • Using water in neutralizing fixing-agents (experts) • Disposing dye solutions (experts) • Using water excessively (experts) • The use of a huge quantity of water to produce a small amount of batik (craftsmen) 	Lack of understanding and excessive water behavior reflects the lack of knowledge and technical skills of batik workers regarding water importance. Therefore, education in the form of training and workshops is needed to address the situation and raise the craftsmen's awareness.
2	<ul style="list-style-type: none"> • The need of Standardized Operating Procedure (SOP) for batik production (experts) • The need of water measurement for batik production (experts) 	The SOP is a "guidebook" for batik craftsmen in using production resources, including measurement to monitor water use during production.
3	<ul style="list-style-type: none"> • The need of green industry implementation for batik SMEs (experts) • The need of green product certification for batik SMEs (experts) • The need of incentives for batik SMEs that certified as green batik SMEs (experts) 	Green batik certification is important to control the batik quality by examining whether the production meets certain indicators of green batik assessment or not; included whether the production process meets the green industry criteria or not.
4	<ul style="list-style-type: none"> • Improving water quality by reducing hardness or demineralizing the water before its use for production (experts) • Improving the dyeing technology (experts) • Providing water technology, particularly to recycle the wastewater (craftsmen; experts) • Using less consuming-water materials (craftsmen; experts) 	Appropriate technology is important to improve water quality, dyeing technology, and recycling the wastewater.

307

308 According to Table 6, the first issue that needs to be addressed relates to the batik craftsmen. Although the
 309 craftsmen understand the importance of water in production, they are not very likely to conserve water. This is
 310 due to a lack of understanding in conserving water because the craftsmen think they could it quite easily and for
 311 free. Training is vital to help them measure the water used and the cost incurred to change this mindset. Moreover,
 312 they can understand how much water is used to produce a sheet of batik and the money spent and know that
 313 expenditure has not been incorporated into their product. Shiva (2002) highlighted water as common goods,
 314 emphasizing that no one could privatize or sell it. However, this understanding leads to excessive use of water by
 315 the craftsmen. Although water is a public good, this term possibly relates to its domestic roles but not production.

316

317 **Discussion**

318 In economics, natural resources is capital which is required as production of goods. In times when the natural
319 resources diminishes gradually, even to scarcity, the use of those resources should be led to a more efficient way.
320 Although efforts have been put to improve resource efficiency, the linear production pattern of take-make-dispose
321 still implies an inefficient resource use disposal (Ellen MacArthur Foundation, 2013). Furthermore, there is still
322 less concern in designing material leakage and disposal (Ellen MacArthur Foundation, 2013). The concern on
323 circular economy has been emerging, mainly because the regenerative system is involved in design to replace the
324 linear or end of life concepts through restoration and elimination of waste and toxic chemicals (Ellen MacArthur
325 Foundation, 2013). In the loom of global water crisis issue, the circular economy paradigm becomes relevant and
326 should be achievable because it involves slowing, closing, and narrowing the loop of materials and energy to
327 minimize resource input and waste emission, and energy leakage (Geissdoerfer et al., 2017). In the context of
328 batik production, the common end of pipe approach that focuses on managing the wastewater as well as its
329 treatment and its disposal after the process is irrelevant to circular economy, because the water should be recycled
330 and reusable for the production. In regard to efficiency, concern on water should not be focused based on the end
331 of pipe approach, but since the openings of the pipe.

332 In general, the results show how the experts reflected their own experience with batik craftsmen regarding to the
333 water use. They agreed that water is the main and important resource for batik production, which could affect the
334 sustainability of batik. When water is unavailable, batik would not produced continuously. Furthermore, the water
335 use of batik craftsmen was explored deeper by the experts by identifying the craftsmen's habit or behavior. The
336 experts explained the water quality preferred by batik craftsmen for production, how the craftsmen usually use
337 the water and why they use the water in their manner. Based on their personal experience with batik SMEs across
338 Indonesia, they could provide information that batik craftsmen are usually use water immeasurably, and relates
339 their habit to the low cost or even free cost of water.

340 This study shows that a lack of understanding of batik and environmental issues and knowledge could affect batik
341 craftsmen's habit. According to Yaacob et al. (2015), batik entrepreneurs in Kelantan, Malaysia, had some
342 awareness on environmental issues, though it depended on respective individuals. This is in line with the previous
343 finding in the batik industry in Jarum, where some craftsmen practiced eco-friendly attitudes in various aspects,
344 such as reusing the wax and harvesting rainwater (Handayani et al., 2020; Handayani et al., 2021). Therefore,
345 providing education through training and workshops continuously improves batik craftsmen's habit of using water
346 because the cognitive aspect is reported to influence environmental awareness (Fraj & Martinez, 2007; Ham et
347 al., 2015; Mei et al., 2016). Guarino (2017) stated that education help raises the awareness of businessman,
348 households, farmers, entrepreneurs, and policymakers, particularly when the water scarcity issue is involved. In
349 this case, education is needed to increase the knowledge of batik craftsmen and help them understand when to use
350 freshwater other materials.

351 Apart from increasing awareness of batik craftsmen, creating SOP implemented in Indonesia is also essential.
352 Although the Ministry of Industry and Trade (2019) has regulated the use of green batik production resources, the
353 regulation still focuses on the dyeing process. The water used for wax removal and washing is left unexplained.
354 In general, the water for wax removal and washing is used in the highest portion. According to the previous study,
355 575 L/day was consumed for washing (Handayani et al., 2018), while Hossain & Khan (2017) reported the water
356 footprint from the wet process (fabric dyeing, washing, and finishing) contributes 62.85% of the total water
357 footprint of textile production in Bangladesh.

358 It is common to find water use studies based on direct water use (Susanty et al., 2015). However, the direct water
359 use approach could not reflect the water used to dilute the wastewater. This means the water consumption reflected
360 by the water footprint approach can be higher than the direct water use. Xu et al. (2018) established that the Blue
361 Water Footprint (BWF) of 25 industrial sectors in Dalian contributes 65.42% of the total water footprint, while
362 34.58% was contributed by the Grey Water Footprint (GWF), indicating the volume of freshwater required to
363 assimilate pollutants. Hossain & Khan (2017) reported that in the textile industry, BWF for knit and woven
364 products were 102 and 130 million m³, respectively, while the GWF was 600 and 858 million m³. From 2001 to
365 2010, the highest BWF of China's textile production was 1.09 Gm³/year in 2007, while the highest GWF was 62
366 Gm³/year (Wang et al., 2013). The previous study also showed a higher portion of GWF in batik production
367 (65,207 L/day) than the BWF, which was 234 L/day (Handayani et al., 2019). These imply that in textile
368 production, the GWF tends to be higher than the BWF. This is attributed to the fact that textile production uses
369 much water for most processes (Kant, 2012). Apart from water, chemicals are used in its processing, and the
370 dyeing contributes 15-20% of wastewater flow (Kant, 2012).

371 The certification of green batik and its incentives provided by the government for the green batik SMEs may
372 encourage the batik craftsmen to move into cleaner production. In this respect, the product quality and its

373 production could be monitored and evaluated by a government agency. Hoekstra (2014) highlighted the
 374 importance of water use sustainability throughout the supply chain, formulated its consumption, targeted pollution
 375 reduction, and implemented the plan to achieve water stewardship targets. The green industry for batik is a policy
 376 implemented by the government in order to push batik SMEs to move forward to green production, including
 377 water friendly production which focus on water use efficiency and minimized water pollution. In a more technical
 378 level, SOP becomes an important part to monitor and evaluate the process of batik production in order to ensure
 379 that production meets the indicators of green batik.

380

381

Figure 2. Aspects that influence the water-friendly batik production

382 This study showed that technology is required to increase water use efficiency. Innovation for efficient use of
 383 resources, including water, is important in circular economy-based textile production (Ellen MacArthur
 384 Foundation, 2017). However, Tonda & Susan (2015) established that new technology requires specific knowledge
 385 and skills. This is challenging in developing countries with low education levels in science, engineering, and
 386 technology. In general, not all technology is suitable for batik SMEs, especially those categorized as advanced.
 387 Appropriate water technology in terms of simplicity, ease of usage and maintenance, and cheap are suitable for
 388 batik craftsmen.

389 Figure 2 shows four aspects which influence the water use for batik production. It is clear that in order to realize
 390 water friendly batik production, the role of batik craftsmen is essential, particularly because they are the main
 391 actor in the process and they are the decision maker in the process that takes place. Therefore, education for
 392 building the capacity of the craftsmen is either important. It is the role of higher education in collaboration with
 393 the government to increase the capacity of batik craftsmen. The capacity building of craftsmen should be
 394 accompanied by providing a suitable work system which functions as quality controller in order to realize the
 395 water friendly batik production. This is the essential part of the government by the implementation of green batik
 396 industry policy. Next, the role of technology as innovation to help the human being solve their problem cannot be
 397 separated from the system and actor. Appropriate technologies in wastewater treatment and dyeing process will
 398 be necessary to be involved in realizing the water friendly batik production, and this will be the responsibility of
 399 scientists in Indonesia, both of government institutions and of higher education. Finally, we conclude three key
 400 factors, i.e. actor-system-technology, that influence the water use for batik production. Building the capacity of
 401 batik craftsmen, ensuring the green batik working system, and providing appropriate water technology are core to
 402 the realization of water-friendly batik production. Future research will be focused on examined the environmental
 403 awareness of the batik craftsmen and building their capacity, as well as introducing the green batik policy to the
 404 batik SMEs.

405 **Conclusion**

406 Four aspects that need to be addressed in order to realize water friendly batik production have been identified, i.e.
 407 educating batik craftsmen to increase environmental awareness collectively, ensuring water use monitoring and

408 evaluation, controlling product quality through green batik certification, and introducing appropriate water
409 technologies to the craftsmen. Those four aspects could be summarized into three key factors, i.e. the actor that is
410 represented by batik craftsmen, while the monitoring, evaluation, and product quality control are represented by
411 the system, and the last is the role of water technology. Well educated and skilled craftsmen along with good
412 system and appropriate technology will would be important to the realization of circularity of water for batik
413 production. This study contributes an insight on how water is utilized in the traditional batik-making process in
414 Indonesia which is still understudied so far. Detailed accounts on factors determining the water use in the industry
415 provides a new understanding on the interaction among factors as well as the importance of each factor. On the
416 empirical side, these new understandings can be used as a guideline for the stakeholders to use the water resources
417 in a more sustainable way. Due to the fact that most of traditional batik industries are small scaled and located in
418 a cluster with a limited stock of water, a communal water management model will be a suitable option. The
419 implementation of communal water management model along with monitoring system by the decision makers
420 will support the industry in coping with the increasing water needs due to the ever-increased market demand of
421 the product and realizing a greener batik industry.

422 **Declarations**

423 *Ethics approval and consent to participate*

424 The authors declare that the participants in this study is agree to participate for this study. Prior to data collection,
425 a letter (in Indonesian) signed by Prof. Dr. Budi Widianarko from Soegijapranata Catholic University -as the
426 person in charge for this research- was sent to each participant in order to ensure their willingness to participate
427 in this study. The letters are well documented and will be provided in case the journal needs the corresponding
428 letters.

429 *Consent to publish*

430 Not applicable, as the identity of all participants for this study was not mentioned specifically in this manuscript.
431 The profession as experts in batik or wastewater was mentioned without specifically mentioned their identity, e.g.
432 their name.

433 *Availability of data and materials*

434 The authors declare that all data included in this published article are in the form of analysed data, while the
435 datasets in the form of Focus Group Discussion recording and transcript are not included in this study. The datasets
436 analysed during this current study (in Indonesian language) are available from the corresponding author upon a
437 reasonable request.

438 *Competing interest*

439 The authors declare that there is no competing interest.

440 *Funding and acknowledgment*

441 The authors express gratitude to the Directorate of Research and Community Service, Directorate General of
442 Research Enhancement and Development, the Ministry of Research, Technology and Higher Education
443 (KEMENRISTEK DIKTI) of Indonesia, which supported this study by Hibah Pasca Doktor grant under the
444 Contract No. 010/L6/AK/SP2H.1/PENELITIAN/2019 and 010/LL6/SP2H.1/AMD/PENELITIAN/2020.

445 *Author contributions*

446 All authors contribute to the manuscript with specified contribution of AP in analyzing and interpreting the
447 importance of water for batik production, BW performed the analysis and interpretation for water source and
448 water use behavior, while WH analyzed and interpreted the key factors that influence water use, efforts to reduce
449 water use, arranged the model, and also the major contributor for the writing. All authors have read and approved
450 the manuscript prior to submission.
